Code 1 description:

This script reads an exoplanet catalogue from a CSV file using pandas and filters out planets with missing mass or radius values. The planets are then classified into three categories (Small, Medium, and Large) based on their mass in Jupiter masses. Finally, a scatter plot of planet mass versus planet radius is generated using matplotlib, where each planet is shown with an “x” marker and color-coded according to its mass category.

Output:

Code 2 description:

This script loads an exoplanet catalogue from a CSV file and removes entries with missing orbital period, semi-major axis, or host-star temperature values. It then visualizes the data using two plots: a scatter plot showing the relationship between orbital period and semi-major axis, and a histogram illustrating the distribution of host-star effective temperatures. These plots help explore orbital properties of exoplanets and the temperature range of their host stars.

Outputs:
